Biodiversity Research Programme (BRP) for Development in Mindanao:  
Focus on Mt. Malindang and Environs

The Biodiversity Research Programme (BRP) for Development in Mindanao is a collaborative research programme on biodiversity management and conservation jointly undertaken by Filipino and Dutch researchers in Mt. Malindang and its environs, Misamis Occidental, Philippines. It is committed to undertake and promote participatory and interdisciplinary research that will promote sustainable use of biological resources, and effective decision-making on biodiversity conservation to improve livelihood and cultural opportunities.

BRP aims to make biodiversity research more responsive to real-life problems and development needs of the local communities, by introducing a new mode of knowledge generation for biodiversity management and conservation, and to strengthen capacity for biodiversity research and decision-making by empowering the local research partners and other local stakeholders.

## Acknowledgment

The arthropod faunal diversity team expresses sincere thanks to the Netherlands Ministry for Development Cooperation (DGIS) through SEARCA for the financial support; to the Joint Programme Committee (JPC) for the well-administered biodiversity program; to the National Support Secretariat (NSS) and Site Coordinating Office (SCO) personnel for their guidance and coordination; to the President of Central Mindanao University (CMU), Dr. Mardonio M. Lao and the administration for the support and concern to the researchers; to the Philippine Working Group (PWG) for their comments and suggestions; to Dr. Ireneo I. Lit, Jr. for the identification of the arthropods belonging to group Phasmatodea (walking sticks), Formicidae (ants), Araneida (spiders), and some of the Hymenoptera (bees and wasps) species; to the Project Leaders of the Terrestrial Ecosystem Master Project, Dr. Jose B. Arances and Prof. Edgardo C. Aranico for their support and distinguished ideas; to the local researchers and laborers who provided their time, effort, and technical assistance during fieldworks in collecting arthropod faunal specimens; and to the provincial and municipal officials of Misamis Occidental especially the barangay captains and members of the local community of the study sites for the protection and accommodation extended to the researchers during the conduct of the study.

---

## Abstract

An assessment of arthropod diversity and analysis of the interrelationships with other resources were conducted in 10 barangays in Oroquieta City, Don Victoriano, Lopez Jaena, and Calamba, Misamis Occidental from June 2003 to May 2005.

The current inventory of Mt. Malindang arthropods includes 741 species in 340 genera, 135 families, 21 orders, and 5 classes. The most speciose orders, the Coleoptera, Hemiptera, Hymenoptera, Diptera, and Araneida account for 78.37 percent of all the species.

Arthropod species diversity is generally higher in forest ecosystems than in agroecosystems. When treated per vegetation and per site, diversity is highest in the mixed dipterocarp forest of Peniel, Lopez Jaena, with 82 restricted species (60% beetles) out of 316 species.

In terms of species composition, three major clusters of similarity among vegetation types are discernible: a) five agroecosystem sites in Gandawan, Mansawan, Lake Duminagat, Mamalad, and Mialen, with Gandawan and Mansawan having the most similar arthropods; b) montane-mossy forest and agrocereal grass-dominated type and almaciga forest in Sebucal; and c) mixed lowland dipterocarp-plantation forests, agrocereal, agroforest, and mixed dipterocarp forest. Three vegetation types appeared to show little species similarities among each other or with any of the three clusters,

namely, the lowland dipterocarp forest (Mialen), submontane dipterocarp forest (Mt. Capole), and agrocereal grass-dominated system (Peniel).

In terms of proportional representation of the trophic guilds of the selected taxa, phytophagous occupies the biggest proportion, followed by the predaceous, pollinators, parasitoids, scavengers, xyloborous, and ant species.

Some species of arthropods are utilized in various ways. The honeybee, *Apis cerana*, produces honey that is popularly sold in the market today. Some consumers even prefer buying bottled honey with beehives submerged in it. Other arthropods like crabs, termites, and the larvae and adults of coconut beetles are utilized as food. Termites and naiads of Odonata are used as fish baits, while ants act as biocontrol agents for cabbage worms. Indigenous knowledge on arthropod species is very scarce and limited only to common uses of honey, butterfly color symbols, "weather forecasting" by *kalong* (crabs), ritual for tree blooms for honey foraging, and predation of a vespid wasp, *Ropalidia* sp. on the larvae of diamondback moth.

Out of 67 (mostly curculionid beetles) endemic arthropod species, at least 21 are associated with 18 endemic host plants in Mt. Malindang, a situation urging immediate conservation efforts.

---

## Introduction

The arthropods are known for their great importance in the living world. Aside from their socioeconomic significance, they have essential roles within ecosystems. Despite their performance of these substantial functions, conservation studies on the arthropod fauna aspects of Mt. Malindang are not yet available.

An inventory of the various aspects of arthropods, especially the entomofauna may show the unique position of Mt. Malindang, as well as the significant relationship of these living creatures to vegetation zones, elevational range, and formulation of participatory conservation strategies.

## Review of Literature

Arthropods are the major invertebrate life forms which far outnumber all other terrestrial animals. The most spectacular variation has been within the insects, constituting 75 percent of all animals (Daly *et al.* 1998; Triplehorn and Johnson 2005). Coleoptera (beetles) - the largest insect order - comprise almost 40 percent of the described insects (Gullan and Cranston 2000), while Curculionidae - one of the beetle families - constitute 5 percent of all animal species (Brusca and Brusca 2003).

The current inventory of Philippine insects includes about 21,000 species in 6,185 genera and 499 families, with an overall endemism of 69.8 percent. Of these, the neuropteroids (beetles, twisted-winged flies, antlions, lacewings, owlflies) account for 35.7 percent of the total insect species, followed by the panorpoids (flies, fleas, butterflies, moths, caddisflies) - 29.3 percent, Hymenoptera (ants, bees, wasps) - 14.3 percent, the hemipteroids (barklice, thrips, lice, planthoppers, leafhoppers, cicadas, true bugs) - 14.2 percent, the orthopteroids (grasshoppers, katydids, crickets, pygmy locusts, preying mantis, stick insects, earwigs, stoneflies, termites, roaches, webspinners) - 4.8 percent, the palaeopterans (mayflies, damselflies, dragonflies) - 1.5 percent, and the rest comprise 0.25 percent (Gapud 2005).

Selected groups of Philippine insects demonstrate high species richness and high levels of endemism (Gapud 2005): damselflies (186 spp), 85.5 percent endemism; pachyrrynchine weevils (352 spp), 95 percent

endemism; butterflies and skippers (890 spp, 900 subspecies), 39.3 percent endemism; *Rhagovelia* (Veliidae, water bugs, 60 spp), many island endemics; caddisflies (Trichoptera, 319 spp), 96 percent endemism; stick and leaf insects (207 spp), 86.5 percent endemism; and *Henosepilachna* (Coccinellid beetles, 20 spp), 55 percent endemism (Bielawski 1965).

Approximately half the species of insects are phytophagous. However, the impact of insect feeding is checked by natural enemies and ameliorated by varied plant defenses. Not all relationships, though, are injurious to plants. About 80 percent of the known flowering plants owe their dispersal to pollination by insects (Lawrence 2004; Daly *et al.* 1998). A good number of arthropod groups are among the principal predators of other invertebrates. Consequently, they are major components in the diets of many terrestrial animals. Thus, arthropods play a very crucial role in food webs of practically all ecosystems (Brusca and Brusca 2003).

The Curculionids referred to as weevils have 41,000 species which are phytophagous as adults and larvae. They probably utilize almost monocotyledon and dicotyledon families, as well as various gymnosperms, ferns, and cycads. Adults feed mainly on young, tender leaves or shoots, flowers, pollen, and fruits. They are usually polyphagous and may feed on an extremely wide range of hosts in unrelated families, and often in forest litter, although their biology is still a matter of speculation (Madge *et al.* 2000).

---

The pollinators ensure full harvest and seed production from many agricultural crops including many orchard fruits, nuts, clovers, vegetables, and cotton (Triplehorn and Johnson 2005). They are essential components of the habitats and ecosystems that many wild animals rely on for food and shelter (Pollinator Declines 2001).

Dragonflies and damselflies are not only known for their predatory role but most of them are sensitive to pollution and favor a wide range of microhabitats. They indicate water quality and since these species prey on mosquitoes, their presence implies lesser mosquito population (Olber *et al.* 2000). Local faunal composition may be strongly affected by any change in water flow, turbidity, or aquatic or waterside vegetation. Inland fishermen identify dragonfly larvae as "mud eyes" and use them as baits while the adults are a minor food item in some countries (Trueman and Row 2001).

The parasitic Hymenoptera are a highly successful and important group of insects comprising probably over a million species. Despite the vast amount of research that has been carried out on the group over the last 100 years or so, there are still many unexplained aspects of their increasing demand for biological methods for pest control and their possible use as natural enemies. Parasitic wasps are tremendously important in research, on pollution dynamics and on host-parasite interaction (Quicke 2003).

According to Perlman and Paskowitz (1998), a new focus on intensive study of as many species as possible in limited areas, rather than coming up with the traditional haphazard description of new species one or few at a time may enable biologists to understand in detail how speciose tropical insects are, their pattern of distribution, and how they interact with other ecosystems to achieve a reasonably comprehensive level of knowledge.

Agriculture, especially monoculture has affected the natural biodiversity through the simplification of habitats and ecosystems. As a result, the loss of floristic and structured diversity leads to the reduction of faunal heterogeneity. It is in this direction that strategies could be useful in restoring or at least improving local species diversity, in terms of flora and fauna (Altieri 1991 as cited by Ceniza 1995). The key is to identify the type of biodiversity that is desirable to maintain and/or enhance in order to carry out ecological services, and then to determine the best practices that will encourage the desired biodiversity components. The role of agroecologists should be to encourage those agricultural practices that increase the abundance and diversity of above- and below-ground organisms, which in turn provide key ecological services to agroecosystems (Altieri and Nicholls 2005).

---

## Rationale

This study was geared towards knowledge generation using the participatory approach to create a better understanding of the diversity and availability of critical arthropod faunal resources in Mt. Malindang. These critical resources include the economically important, threatened, and abundant species. Efforts were directed on analysis of the interactions of the multifarious factors that affect and influence

these resources. An assessment of the scientific and indigenous knowledge systems on biodiversity conservation was also conducted. The ultimate goal was to identify, recommend and develop concrete strategies to enhance the capability of the local communities and other stakeholders towards the conservation and sound management of Mt. Malindang's biodiversity resources.

## Objectives

The general objective of the study was to develop a better understanding of the landscape and management of the critical arthropod faunal resources in Mt. Malindang through assessment of the existing arthropod diversity resource and analysis of the significant interrelationships of the arthropod fauna with other resources in the area.

The specific objectives of the study were to: (1) identify the arthropods in the forest and agroecosystems in Mt. Malindang; (2) determine the richness and endemism of the arthropod faunal species; (3) identify the biodiversity parameters for designing appropriate conservation and management schemes of

critical resources; (4) assess the impact of socioeconomic-cultural activities on the arthropod biodiversity resource use; (5) harmonize indigenous knowledge system (IKS) in designing monitoring system for arthropod diversity resource use and conservation practices; (6) organize a network of stakeholders in various communities for the implementation of scientifically harmonized IKS monitoring and conservation practices; (7) promote awareness on arthropod resource diversity and conservation; and (8) develop additional integrated development and biodiversity conservation strategies in local biodiversity conservation for local communities.

# Methodology

## Site selection

Seventeen sites with 10 subsites were established as research areas for the arthropod fauna study (Table 1). The different sites were located within the barangays of Lake Duminagat, Gandawan, and Mansawan of Don Victoriano; Old Liboron, Sebucal, Mialen, Toliyok, and Bunga of Oroquieta City; Peniel of Lopez Jaena; and Mamalad of Calamba, Misamis Occidental.

The sites were categorized according to vegetation types with partial reference to altitude. North Peak at altitudes of 1,800-2,185 meters above sea level (masl) and Mt. Ginlajan at 1,700-1,900 masl are mossy forests. Mt. Uohan sa Dapitan at 1,450-1,700 masl and Mt. Pungol at 1,400-1,600 masl are montane forests. Old Liboron at altitudes of 1,200-1,400 masl is an almaciga forest. Mt. Capole at 900-1,100 masl is a submontane dipterocarp forest. Sites 11 in Peniel and 16 in Mamalad at altitudes of 450-900 masl are mixed dipterocarp forests. Sites 13 in Mialen and 16a in Mamalad at altitudes ranging from 220 to 500 masl are lowland dipterocarp forests. Site 15 in Toliyok at 220-450 masl is a mixed lowland dipterocarp forest. Sites 11a in Peniel and 19 in Bunga at altitudes of 120-900 masl are plantations or degraded forests.

Ten subsites (north and south exposures) were established at the research sites of North Peak, Mt. Uohan sa Dapitan, Mt. Capole, site 13 in Mialen, and site 15 in Toliyok.

The other sites located in barangays Lake Duminagat, Mansawan, Gandawan, Sebucal, Mialen, Toliyok, Bunga, Peniel, and Mamalad at altitudes of  $\pm$ 1,000 masl were categorized as agroecosystems which were either planted to vegetables, cereals or are agroforests and grass-dominated fallowed areas.

## Establishment of Sampling Plots

Sampling plots with a dimension of 20 x 20 m along the N-S transect were established at every 250 m change in elevation and 500 m horizontal distance between plots using GPS or altimeter. Based on elevation gradients, the south or north

slope exposure had two sample plots along the N-S transect, representing center plots. One sample plot on each side of the center plot at the distance of 500 m was prepared. A total of six sample plots were, therefore, established.

## Sampling Procedure

**Visual Sampling.** In every 20 x 20 m plot, one 1 x 1 m quadrat was established at the upper right corner of the main plot. However, if this quadrat was not an ideal site, another site within the plot was selected. The plants in this quadrat were examined for the presence of arthropods. Visual sampling started from the lower to the upper part of the plants. Sweep nets were used for collecting flying insects.

Arthropods were counted and recorded according to species. Samples of each species were taken as voucher specimens.

**Sweep Net Sampling.** For grasslands and agroecosystems, systematic sweeps were performed in two intersecting diagonal strips extending from end to end of each 20 x 20 m plot. Catches were sorted, counted, and recorded. Samples were taken as voucher specimens.

**Opportunistic Sampling.** Within the 20 x 20 m forest plots, opportunistic sampling was done. Vertical 250 x 10 m transects between center plots were also utilized for this sampling. Catches were sorted, counted, and recorded. Samples were taken as voucher specimens.

## Threatened Faunal Species

Information of species occurrence and resource use were obtained through key informant interviews and focus group discussions (FGD). These information were needed to validate the data gathered from the field and to verify species that might not have been encountered during actual sampling. A list of threatened species based on sampling results as well as endemic, economically and culturally important species was generated after the conduct of field assessment, semi-structured interviews, and

FGD. The data generated was used in formulating mitigating measures to minimize or eliminate unsustainable resource utilization practices.

## Biodiversity Indices

Data analysis includes the computations of diversity indices to evaluate diversity of arthropod taxa within sites and to assess diversity of the landscape as a whole.

For each of the sampling site, which represented an ecosystem, the following arthropod biodiversity parameters were considered:

**Species Richness.** Species richness refers to the actual number of species as a direct measurement.

**Species Diversity.** Species diversity refers to the number (species richness) and relative abundance of species in a biological community (Campbell *et al.* 2000). Shannon's index of diversity ( $H'$ ) measures the average degree of 'uncertainty' in predicting to what species an individual chosen at random from a collection of S species and N individuals belong. Shannon's index of diversity was computed using the formula:

$$H' = -\{(n_i/n) \ln (n_i/n)\}$$

Where:

$n_i$  = the number of individuals belonging to the  $i^{\text{th}}$  of S of species in the sample

$n$  = the total number of individuals in the sample

**Pearson's Index of Similarity (S).** The Pearson's Index of Similarity (S) is a clustering analysis, measuring the degree to which the species composition is alike or different between and among sites.

**Correspondence Analysis.** Correspondence analysis is a type of ordination to determine community similarity, which uses reciprocal averaging to determine axis values. It is used to describe data consisting counts.

## Socioeconomic-cultural Activities and Biological Properties of the Ecosystem

Workshops with the BRP socioeconomic group were conducted to integrate the findings and relate the socioeconomic data, which were derived from objectives 1, 2, and 3 of the arthropod fauna survey. Consultations with the local community were likewise conducted to validate the data gathered from the field.

## Formulation of Recommendations for Increasing Awareness on Biological Diversity and Conservation

A package of recommendations that contained suggested specific information, education and communication (IEC) materials (e.g., flyers and posters), as well as set of strategies or schemes for the conservation and management of critical resources were prepared. These recommendations were based on field sampling results and information which were obtained through structured interviews and FGDs.

Data gathered especially on threatened and endemic species shall be transported for GIS mapping featuring the need for faunal conservation in selected sites.

---

## Results and Discussion

### Arthropod Composition

The various arthropod taxa of Mt. Malindang Range Natural Park (MMRNP) are shown in Table 2 and Figure 1. Seven hundred forty-one species representing five arthropod classes are recorded. The insects comprise the biggest bulk with 14 orders, namely, Odonata, Ephemeroptera, Blattodea, Dermaptera, Isoptera, Orthoptera, Phasmatodea, Mantodea, Hemiptera, Neuroptera, Coleoptera, Diptera, Lepidoptera, and Hymenoptera, while the Arachnida are represented by Acarina (mites), Araneida (spiders), Phalangida (daddy long legs), and Scorpionida (scorpions). Other classes include Crustacea (crabs), Chilopoda (centipedes), and Diplopoda (millipedes).

The most speciose taxa which account 78.37 percent are the Coleoptera (beetles) with 258 species, Hemiptera (bugs, hoppers, cicadas, etc.) with 157 species, Hymenoptera (bees, wasps, and ants) with 62 species, Diptera (true flies) with 53 species, and Araneida (spiders) with 51 species.

The Coleoptera constitute 34.86 percent of the arthropod species in Mt. Malindang. The Hemiptera ranked second, 21.08 percent, followed by Hymenoptera (8.38%), Diptera (7.16%), and Araneida (6.89%).

The remarkable proportion of Coleoptera in Mt. Malindang is undisputable just like in any Philippine arthropod inventory (Baltazar 2001; Gapud *et al.* 2001; Ceniza 1995) and on any worldwide inventory study (Daly *et al.* 1998; Gullan and Cranston 2000; Brusca and Brusca 2003). Lepidoptera, Hymenoptera, Diptera, and Hemiptera may interchange ranks from second to fifth in various arthropod assessment studies. However, in this study in Mt. Malindang, Lepidoptera ranked seventh since most moths were not included and it was represented by butterflies and skippers only.

The orders Orthoptera (grasshoppers, katydids, crickets), Lepidoptera (butterflies and skippers), Odonata (dragonflies and damselflies), Phasmatodea (stick and leaf insects), Mantodea (preying mantis), and Blattodea (cockroaches)

have corresponding ranks of sixth to eleventh representing proportions ranging from 5.14 percent for Orthoptera to 1.62 percent for Blattodea. A small proportion of the pie chart (0.68%) is represented by two species each of Dermaptera (earwigs) and Neuroptera (lacewings), and one species of Ephemeroptera (mayflies) and Isoptera (termites).

The other arthropods which comprise only 0.84 percent of the pie chart include one species each of Phalangida (phalangids), Acarina (mites), Scorpionida (scorpions), Crustacea (crabs), Chilopoda (centipedes), and Diplopoda (millipedes).

### Endemic Arthropods

The current identification of Malindang arthropod species is ongoing and may take a considerable period to complete, considering that the study of the Malindang components is the first initiative. While current estimates of endemic species show a total of 17 Philippine endemics, 23 Mindanao endemics, and 67 MMRNP endemics, of which 41 species are beetles (Table 3), many more species of arthropods remain to be discovered and described. Out of the 67 endemic arthropod species, at least 21 species are associated with endemic host plants (Table 4).

Out of the 28 species of Odonata (damselflies and dragonflies), six are Philippine endemics and seven are Mindanao endemics. The Philippine endemics include the dragonflies, *Heteronaias heterodoxa* (Selys) (Corduliidae) (Figure 2); *Heliogomphus bakeri* Laidlaw (Gomphidae), and *Diplacina braueri* (Selys) (Libellulidae), as well as, the damselflies, *Vestalis melania* Selys (Calopterygidae), *Rhinocypha turconii* Selys (Chlorocyphidae), and *Prodasineura integra* (Selys) (Protoneuridae).

The Mindanao endemic Odonatans are all damselflies which include *Devadatta podolestoides basilanensis* Laidlaw (Amphipterygidae) (Figure 3), *Cyrano angustior* Hämäläinen (Chlorocyphidae), *Rhinocypha dorsosanguinea* Lieftinck (Chlorocyphidae), and three species of Platycnemididae represented

\* - identified both endemic and threatened host plants by the BRP flora study

\*\* - identified endemic host plants by the BRP flora study

**Figure 1.** Proportional representation of the arthropod groups of Mt. Malindang Range Natural Park (MMRNP) with a total of 741 species.

**Figure 2.** Philippine endemic dragonfly, *Heteronaias heterodoxa* (Selys), Corduliidae.

**Figure 3.** Mindanao endemic *Devadatta podolestooides basilanensis* Laidlaw (Amphiptyergidae).

**Figure 4. Greater Mindanao endemic *Risiocnemis flammea* (Selys) (Platycnemididae).**

by *Coelicia dinoceras* Laidlaw, *Risiocnemis* (R.) *appendiculata* (Brauer), and *Risiocnemis* (*Igneocnemis*) *flammea* (Selys) (Figure 4).

Damselflies in Mindanao are 28 percent endemics while 40 percent are Philippine endemics. The low endemism of damselflies in contrast to the findings of Gapud 2005 might be attributed to sampling site stations where sites were established at least 50 m away from water tributaries/bodies. Majority of endemic damselflies are residents of forested streams and brooks especially the endemic genus *Risiocnemis* (Gapud 2005).

The Orthopteran endemic species include four Philippine and six Mindanao endemic species. The Philippine endemic species include *Melicodes tenebrosa* (Walker) (Acrididae), *Diotarus verrucifer* Stal (Tetrigidae) (Figure 5) and the two species of Tettigoniidae, *Segestes* sp. nr. *vittaticeps* Stal (Mecopodinae), and *Tympanoptera* sp. nr. *philippina* (Hebard) (Pseudophyllinae) (Figure 6).

Out of the six Mindanao endemic Orthopterans, four are Tettigoniidae and one species each for Tetrigidae, *Misythus* sp. nr. *jubatus* Hebard (Figure 7), and Trigonopterygidae, *Systella philippinensis* (Walker) (Figure 8). The Tettigoniidae include *Anthracites* sp. nr. *major* Hebard (Conocephalinae) (Figure 9), *Xiphidiopsis*

*drepanophra* Hebard and *X. gemmula* Hebard (Meconematinae), and *Morsimus* sp. nr. *serratus* Beier (Pseudophyllinae) (Figure 10).

The 24 Mindanao or MMRNP endemic species of Phasmatodea are enumerated in Appendix Table 19. *Orthomeria* sp. 1 represents Aschiphasmatidae; *Euobrimus* sp. for Heteropterygidae; *Phyllum* sp. for Phyllidae (Figure 11); the three species *Phobaeticus* sp., *Pharnacia*(?) sp. and *Baculum* sp. represent Phasmatidae; and the six species, *Lonchodini* sp. 1, *Lonchodes* sp., *Necrosciinae* sp., *Asceles* sp., *Marmessoidea* sp., and *Necroscia* sp. represent Diapheromeridae. Phasmatodea in Mindanao/MMRNP are all endemics. All species remain undescribed.

Out of 156 Hemiptera species of MMRNP, only three reduviid species are Philippine endemics which include *Ischnobaena macerrima* Stal, *Euagoras plagiatus* and *Veleda brevispines* Stal (Appendix Table 20). One treehopper, *Emphusis bakeri* Funkhouser (Membracidae) (Figure 12) is Mindanao endemic. No species is recorded as MMRNP endemic.

From a total of 258 Coleoptera species of MMRNP, three are Mindanao endemics and 41 are MMRNP endemics (Appendix Table 21). The Mindanao endemic species include *Xenocerus striatus* Jordan, Anthribidae; *Nupserha* sp., Cerambycidae; and *Mimoplacia diversenotata* von Breuning, Cerambycidae. The 41 MMRNP endemic species are all Curculionidae (weevils) distributed as follows: two species of *Alcidodes* (Figure 13 A), two Rhynchophorinae, 14 *Metapocyrtus* (Figure 13 B-E), six species of *Pachyrhynchus* (Figure 13 F-I), and Otiorrhynchinae, two *Odosyllis*, and one species each of *Tragopus*, *Calidiopsis*, *Paepalosomus*, *Nauphaeus*, and *Eugnathus*. The other four weevil species are undetermined.

The 41 species of Curculionidae in MMRNP are all considered endemics. This confirms the assessment of Gapud (2005) where the pachyrhynchine weevils are specifically over 95 percent endemics. Although the Malindang pachyrhynchines remain undescribed, all are likely to be endemic to Mindanao.

The 12 endemic butterflies (Lepidoptera) are categorized into four Philippine endemics, six Mindanao endemics, and two MMRNP endemics

**Figure 5.** Philippine endemic tetrigid, *Diotarus verrucifer* Stal.

(Appendix Table 22). The Philippine endemics include *Athyra maenius semperi* (Nymphalidae) and three Papilionidae species, *Menelaides hystaspes* (Figure 14 A), *M. rumanzovia rumanzovia* (Figure 14 B), and *Troides magellanus*. The Mindanao endemic subspecies include *Choaspes plateni adhara* (Hesperiidae) (Figure 15), *Mycalesis ita imelda* (Nymphalidae), and four subspecies of Pieridae, *Delias baracasa baracasa*, *D. henningia ochreopicta* (Figure 16), *Eurema hiurai hiurai*, and *E. sarilata sarilata*. The two MMRNP endemic subspecies are *Parantica dannatti malindangensis* (Nymphalidae) (Figure 17), and *Delias diaphana basilisae* (Pieridae) (Figure 18).

### Arthropod Species Richness and Diversity

Arthropods in Mt. Malindang have varied richness and diversity values as presented per vegetation (Table 5 and Figure 19). The arthropods in the forest vegetation types are generally more diverse than the agroecosystem communities. Higher arthropod diversity indices in forest vegetation types may be attributed to the plant architecture in these types which provide more ecological niches suitable for the establishment of arthropods than the relatively simple set up within agroecosystem communities.

The arthropods are most diverse (355 species,  $H'=2.397$ ) in the mixed dipterocarp forest. This is followed by the arthropods in the mossy forest (169 species,  $H'=2.015$ ) and plantation or degraded forest (136 species,  $H'=2.002$ ). The lowest arthropod species inventory of 30 species with corresponding lowest diversity value of 1.252 is observed in the agro-cereal community. The mixed dipterocarp forest is a patch of the remaining natural forest. Its complex structure may have largely contributed to the high arthropod species richness and diversity. The low diversity of arthropods in the agro-cereal community might have been influenced by the simplicity of vegetation structure in monocultured cereals.

When treated per site (Table 6 and Figure 20), the arthropods in Peniel mixed dipterocarp forest has the richest (316 species) and the most diverse ( $H'=2.348$ ) arthropods while the agro-cereal community in Sebucal has the least diverse ( $H'=0.949$ ) arthropods.

### Arthropod Species Similarity

Comparison of similarities of arthropod fauna among vegetation types is presented in Figure 21. Arthropod fauna are grouped into three main clusters with three outgroups.

The largest cluster is composed of agroecosystem communities. The vegetable-grass-dominated communities of Gandawan, Mansawan, and Lake Duminagat have the closest similarity of arthropods. Gandawan and Mansawan have a similarity coefficient of 0.59, while Lake Duminagat has a coefficient of 0.35. The proximity of these sites may have contributed to the similarity of the species. The arthropods of the agroforest of Mamalad compared to the agroforest-cereal of Mialen have low similarity but their connection to the Mansawan-Gandawan-Lake Duminagat sub-cluster might be due to the presence of common hosts or alternate hosts in these areas.

The second cluster of arthropod species shows the similarity of the species among the mossy, montane and almaciga forests and agro-cereal-grass-dominated communities. The similarity coefficient of 0.5 between the mossy and montane forests as regards species composition indicates proximity of these sites, while the similarity between the agro-cereal-grass-dominated community and the almaciga forest of both Sebucal sites might be due to the presence of almaciga patches near the agro-cereal-grass-dominated communities. The connectivity of these four sites might be due to the more or less equal densities of phalangids recorded in these sites.

The similarities among the mixed lowland dipterocarp of Toliyok and Mamalad, plantation forest of Bunga and Peniel and the agroforest-cereal communities of Toliyok are depicted in the third cluster. These similarities manifested proximity of these areas.

The lowland dipterocarp forest (Mialen), submontane dipterocarp forest (Mt. Capole), and agrocereal-grass-dominated community are considered outgroups as they appear to show little species similarities among each other or with any of the three clusters.

**Figure 19. Species diversity of arthropod fauna per vegetation of Mt. Malindang Range Natural Park (MMRNP).**

A more or less similar grouping of vegetation types is observed when correspondence analysis is used to determine similarity of species composition (Figure 22). The agroecosystem communities except the agroforest form one group. The mossy, montane, almaciga, and submontane dipterocarp forests form another group, while the third group is composed of other forests and the agroforest communities.

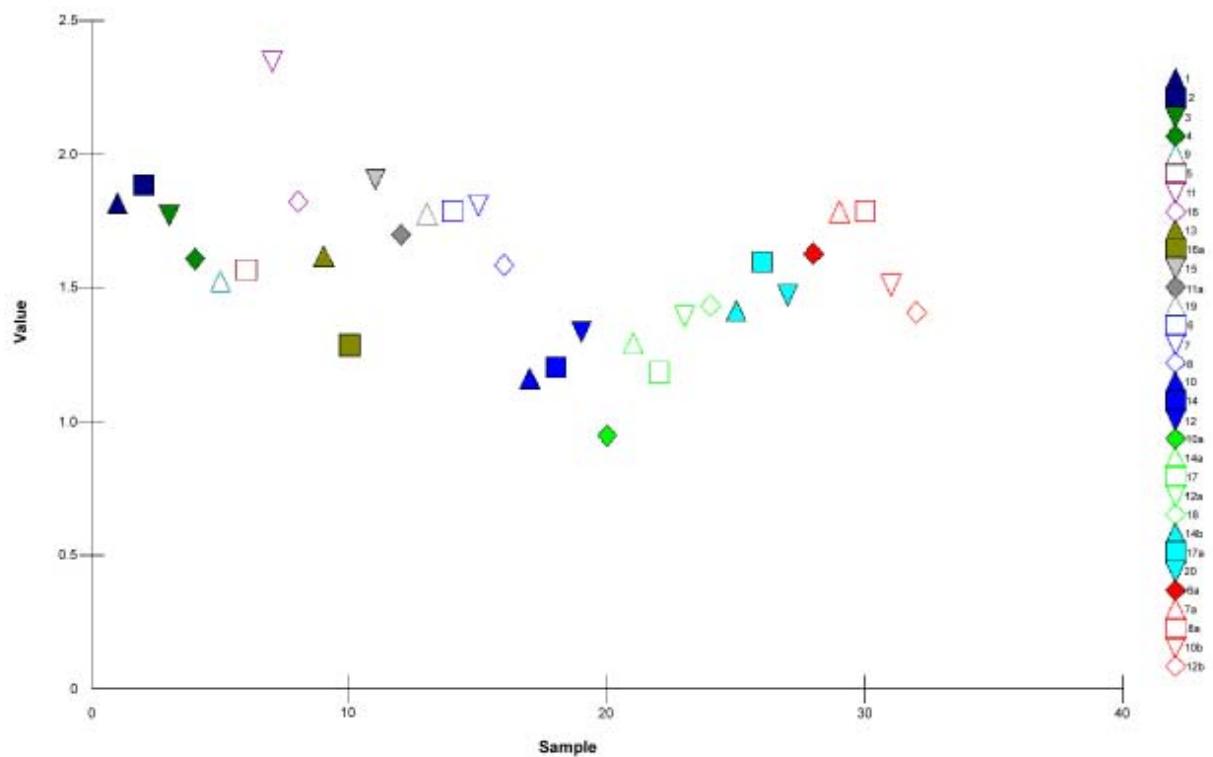

### Trophic Guild Composition

Table 7 presents the number of species per trophic guild of each vegetation type. Knowledge on the biology of Mt. Malindang arthropod species is limited so the assignment of guilds was based largely on the known biology of a few species.

Approximately half of the species of arthropods are phytophagous (Figures 23-26), 26 percent

are predaceous (Figures 27-28), 7 percent are pollinators (Figure 29), 6 percent are parasitoids, 5 percent are scavengers (Figure 30), 3 percent are xyloborous (Figure 31), and 3 percent are ants. Daly *et al.* (1998) referred to this view of phytophagous proportion as related to the other guilds. The relationships of the phytophagous species with their associated host plants are partially dealt with and less efforts were spent on determining the functional relationships between specific predators and preys, parasitoids and hosts, pollinators and flowers, and other relationships. The ants have a diverse range and combination of feeding habits (Daly *et al.* 1998; Stork 1991 as cited by Ceniza 1995) so they are lumped as one guild.

The mixed dipterocarp forest has the most number of phytophagous (136), predaceous (216), xyloborous (7), and ant (15) species. The mossy forest has the most number of

pollinator species (21), agro-vegetable community has 25 parasitoid species while the agro-grass-dominated fallowed community has the most number of scavengers/fungivorous (40) species.

### Arthropod Fauna Resource Utilization

Arthropod fauna are largely represented in almost all types of ecosystems. However, due to their inconspicuousness - most of them are not easily recognized - they were treated with less importance. Research on the utilization of arthropod fauna in Mt. Malindang has shown that these small creatures of varied forms are equally important as the other organisms in the ecosystem.

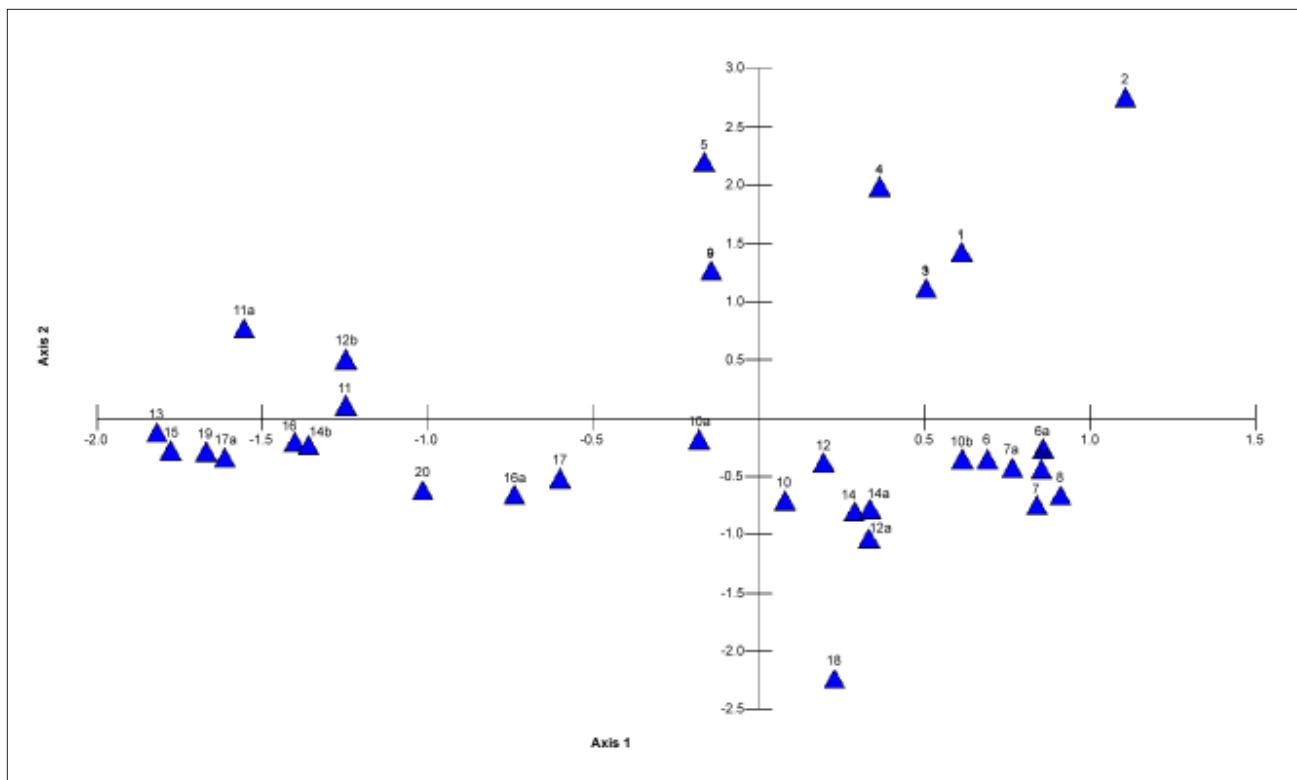

The honeybee, *Apis cerana* is well known for its honey. The male household members in Lake Duminagat, Mansawan, Sebucal, and Peniel are tasked to collect honey for family consumption, especially as medicine for children. If the harvest is about 5-6 bottles of honey per beehive, some

are sold at 100-150 pesos per bottle of 350 ml.

Some beehives containing the larvae are also collected and eaten. In some cases, the larvae are also used to feed chickens, especially the roosters for agility and endurance (as *pampaisog*) during cockfighting.

Termites, *kalong* (crabs), and coconut beetles are utilized as food and source of protein in Burgos, Lopez Jaena. Usually, the larvae and adults of coconut beetles are toasted for viand during mealtime.

The naiads of the Odonata, termites and ants are economically important, too. The naiads called *kadang-kadang* as well as termites are used as baits in fishing. The ants although recognized as playing variable roles in the ecosystem are utilized by vegetable farmers in cabbage-growing sites as control agents against worms (*bitay-bitay*). To attract the ants, they spread coconut *sapal* on cabbage plants.

## **Indigenous Knowledge on Arthropod Fauna**

Indigenous knowledge on arthropod fauna is very scanty that even their common names are unknown to many.

To some, knowledge of the arthropod fauna is limited only to the metamorphosis of butterflies or dragonflies, or honeybees as source of the precious honey. In some areas, fighting cock growers utilize the protein-rich bee larvae as feed additive.

It has been a belief among native folks that a red butterfly hovering around the house signals war or trouble, while a white butterfly symbolizes a coming wedding. A brown butterfly means money, and a black one hints death.

In areas where *kalongs* (crabs) are found, the locals believe that when these kalongs come out of their habitat and seen on elevated areas, it foretells a coming rain. The vespid wasp, *Ropalidia* sp. was observed preying on the larvae of diamondback moth, *Plutella xylostella*.

Blooming of a certain flower is believed to indicate honey production. If this flower fails to bloom, the people in the locality perform a ritual that is said to enhance the blooming of the flower.

## **Conservation Strategies**

Researchers were faced with the challenge of identifying and determining the number of threatened arthropod species of Mt. Malindang. The work on the classification of threatened species with high economic value like honeybees, crabs, and other endemic species, especially those who feed on endemic host plants was done.

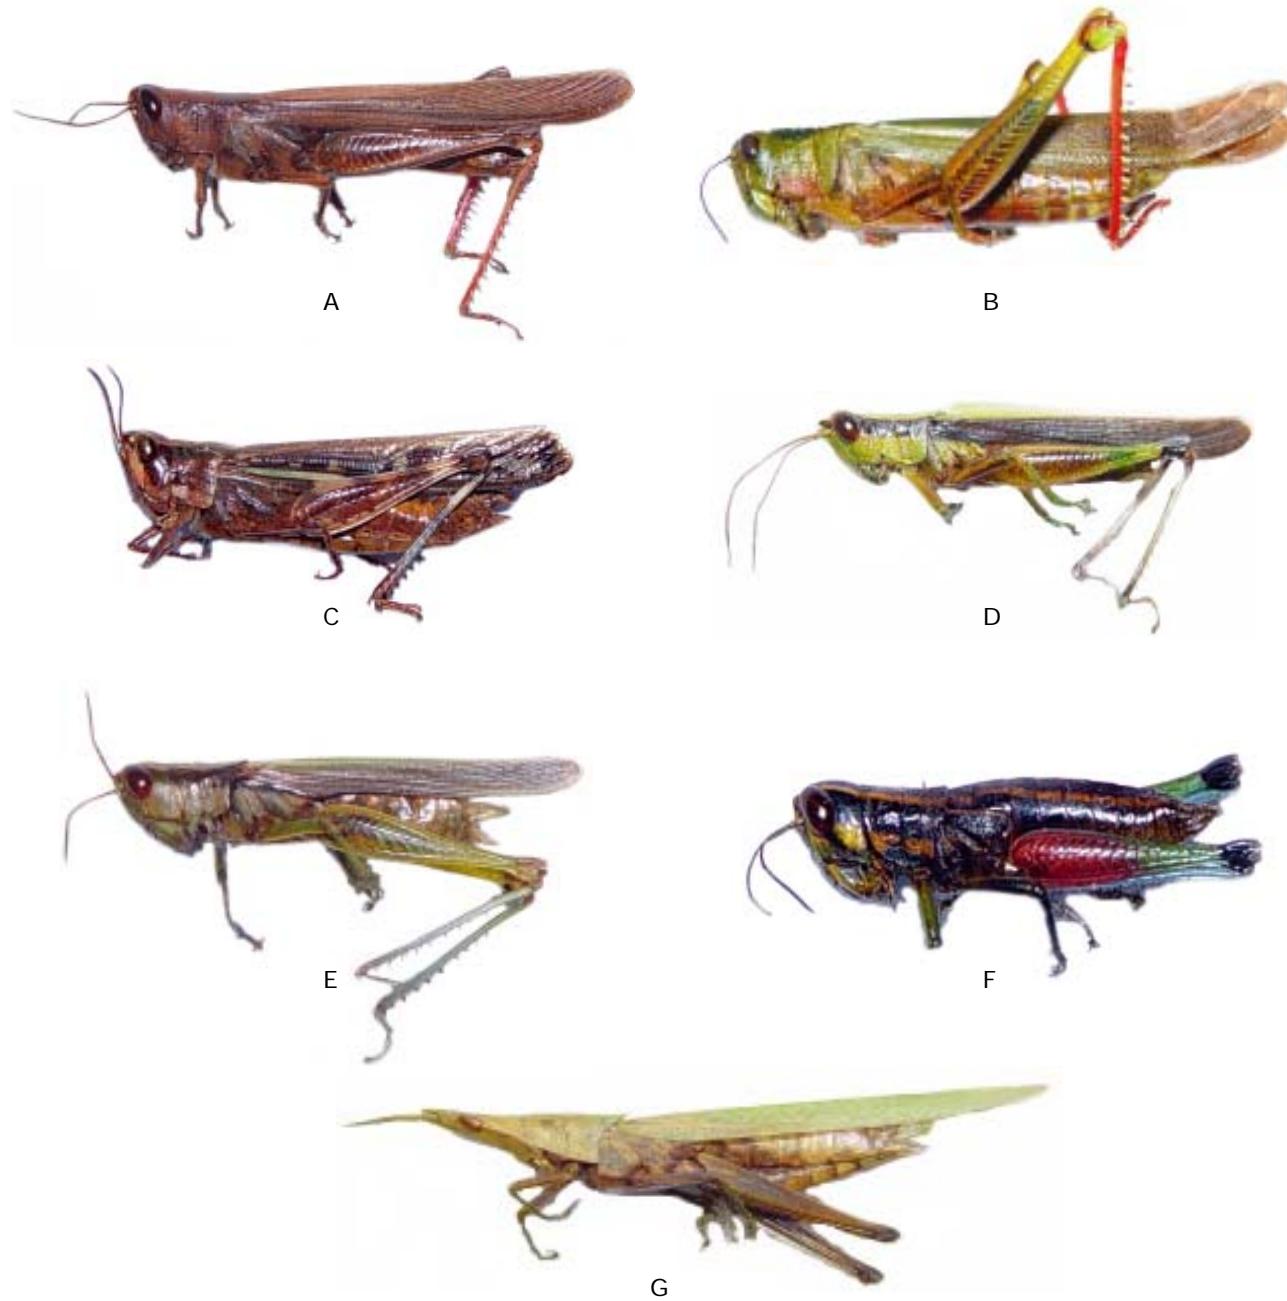

A serious challenge for arthropod researchers is to determine what and how many arthropod species of Mt. Malindang are considered threatened. The population of the honeybees is threatened with indiscriminate harvesting of beehives to obtain honey and larvae of bees. The same threat is faced by the native crabs which are also harvested haphazardly for food. Endemic arthropods, especially the curculionids (beetles) and walking sticks are threatened when associated host plants are not conserved.

While the collection of the basic information on threatened arthropod species remains important, initiatives to protect the identified threatened species must be given high priority. There must be a balance between conservation of plants and vertebrates, which attract public sympathy, and the protection of MMRNP where threatened species of arthropod are still abundant. Every stakeholder may play an important role in the conservation of arthropod habitats. In view of this, arthropod researchers have strong support for any conservation measures for plants and vertebrates. Meanwhile, with the knowledge that management initiatives are targeted to help preserve certain plant and vertebrate species in the park, the local people and development managers should be informed of the threatened arthropod species within. A continuous monitoring for the population of the threatened arthropod species must be implemented.

## Summary

The arthropod fauna study was conducted in 10 barangays in the municipalities of Don Victoriano, Lopez Jaena and Calamba, and the City of Oroquieta. The sites were categorized into vegetation types like mossy, montane, almaciga, submontane dipterocarp, mixed dipterocarp, lowland dipterocarp, mixed lowland dipterocarp and plantation or degraded forests, and the agroecosystem which includes the agro-forest, vegetable, cereals, and grass-dominated fallowed communities.

The study was conducted to attain the following objectives: (1) to identify the arthropod faunal species in the forest and agroecosystems in Mt. Malindang, (2) to determine the arthropod faunal species richness and endemism, (3) to identify the biodiversity parameters for designing appropriate conservation and management schemes of critical resources, (4) to assess the impact of socioeconomic-cultural activities on the arthropod biodiversity resource use, (5) to harmonize indigenous knowledge system (IKS) in designing monitoring system for arthropod diversity resource use and conservation practices, (6) to organize a network of stakeholders in various communities for the implementation of scientifically harmonized IKS monitoring and conservation practices, (7) to promote awareness on arthropod resource diversity and conservation, and (8) to develop additional integrated development and biodiversity conservation strategies in local biodiversity conservation for local communities.

Arthropods have variable responses to weather and often highly seasonal, making it difficult to determine if the variation of the population obtained from the different sites was due to sampling variation or part of the normal fluctuation. Nonetheless, in collaboration with the other studies under the BRP Terrestrial Ecosystem Master Project (TEMP), especially the flora group, methodologies were revised/improved from time to time to obtain a more or less accurate and unbiased picture of the arthropod composition and population in the sites. The location of the 1 x 1 m quadrat for example, was no longer established strictly at the upper right corner of the 20 x 20 m plot but

at any ideal site within the plot. An ideal quadrat is the site which somewhat represents the features of the entire plot.

Among the other employed local controls was the visual counting of the arthropods within the quadrat ahead of the vegetation sampling of the flora group to minimize escape of active species. The systematic sweep net sampling was somehow standardized since it was carried out by the same personnel. The collaborative efforts of the members of the flora group in the familiarization of arthropods had increased input to the data, especially in the opportunistic and transect walk sampling.

A total of 741 arthropod species in 340 genera, 135 families, 21 orders, and 5 classes were inventoried. The 5 classes include Insecta, Arachnida, Crustacea, Diplopoda, and Chilopoda. The Class Insecta made up the biggest bulk of arthropods with Orders Coleoptera (beetles and weevils), Hemiptera, Hymenoptera, Diptera, and Araneida comprising 78.37 percent of the species.

Arthropod species diversity was higher in the forest ecosystem than in the agroecosystem. When treated per vegetation and per site, diversity was highest in the mixed dipterocarp forest, specifically at Peniel, Lopez Jaena with 82 restricted species (60% beetles) out of 316 species.

In terms of species composition, three major clusters of similarity among vegetation types are discernible: a) five agroecosystem sites in Gandawan, Mansawan, Lake Duminagat, Mamalad, and Mialen with arthropods most similar between Gandawan and Mansawan; b) montane-mossy forest and agrocereal grass-dominated type and almaciga forest in Sebucal; and c) mixed lowland dipterocarp-plantation forests, agrocereal agroforest, and mixed dipterocarp forest. Three vegetation types appeared to show little species similarities among each other or with any of the three clusters, namely, the lowland dipterocarp forest (Mialen), submontane dipterocarp forest (Mt. Capole), and agrocereal grass-dominated system (Peniel).

Proportional representation of the trophic guilds of the selected taxa indicated biggest proportion of the phytophagous, followed by the predaceous, pollinators, ants, parasitoids, scavengers, and xyloborous species.

The honeybee, *Apis cerana* is a well-known source of honey. Other arthropods providing direct benefits include larvae and adults of coconut beetle as food, termites and naiads of Odonata as fish baits, and ants as “biocontrol agents” (as an attractant) against cabbage worms.

Bits of indigenous knowledge on arthropods were gathered. A few examples include uses of honey, butterfly color symbols, “weather forecasting” by *kalong* (crab), and ritual for tree blooms for honeybee foraging, and predation of a vespid wasp, *Ropalidia* sp. on the larvae of diamondback moth.

An over all species endemism was assessed at 9 percent. Out of 67 (mostly curculionid beetles) endemic arthropod species, at least 21 species are associated with 18 endemic host plants, indicating urgency of conservation efforts. These endemic species are probably new species and new records, which remain undescribed.

## Conclusions

The following conclusions are drawn from the results of the study:

- With the voluminous arthropod species in Mt. Malindang, some species are still undescribed and unidentified.
- An estimate of 741 arthropod species in this current inventory ignores the canopy and litter arthropod species, therefore, more species are yet to be accounted. The association of endemic arthropod species with endemic host plants show coexistence of these organisms.
- The generally higher arthropod species diversity in forest ecosystems (specifically the mixed dipterocarp forest) than in the agroecosystem is a manifestation of higher habitat and food resource diversity in the forest. There is no established pattern between diversity and altitude. The proximity of vegetation types provides higher percentage similarity of arthropod species.
- Knowledge on arthropod resource use is minimal and is limited to species with direct economic importance like honeybees and crabs. Arthropods, especially insects, are generally viewed as destructive organisms.

---

## Recommendations

The following recommendations are provided:

- Taxonomic identification of the still unidentified species is necessary. It is suggested that further study along this aspect should be conducted to have a more detailed inquiry of all the species of the different groups.
- More collection efforts should be exerted to obtain year round samples of arthropods which should include canopy and litter arthropod species. Promotion of life history studies of selected groups for biodiversity conservation is also recommended. Conservation of endemic host plants is necessary to conserve endemic arthropods as well.
- Species diversity should be maintained or increased, taking into consideration, the plant architecture in the area. Structurally complex plants support more species due to greater diversity of habitat and food resource.
- Information dissemination regarding arthropod resource use is recommended. Posters, brochures, films, exhibits, and other IEC materials should be developed for awareness campaigns on the importance of arthropods and biodiversity. These materials should also include information on the current status of economic species, endemic species, beneficial and destructive species of arthropods in Mt. Malindang Range Natural Park.
